## INTRODUZIONE

Nel 2011 in alcune aree dei comuni di Treviso, Casier, Preganziol e Quinto di Treviso è stata riscontrata la presenza di mercurio con valori superiori al limite di 1 microgrammo/litro stabilito dalla Direttiva 98/83/CE sulla qualità delle acque destinate al consumo umano. La Giunta Regionale ha così affidato ad ARPAV un monitoraggio d'indagine ai sensi del D.M. 260/2010<sup>1</sup>. ARPAV ha approvato lo schema di convenzione tra i due Enti ed ha istituito il progetto denominato MeMo (**M**onitoraggio d'indagine del **M**ercurio nelle acque sotterranee in provincia di Treviso)<sup>2</sup>. Il progetto si è concluso nel 2013 e la relazione conclusiva è disponibile sul sito internet dell'Agenzia<sup>3</sup>.

Dal 2014, per tenere sotto controllo l'evoluzione della contaminazione, sono state realizzate tre campagne di monitoraggio all'anno su una ventina di punti individuati tra quelli della rete di controllo del progetto MeMo. Anche in questo caso i risultati sono disponibili sul sito internet<sup>4</sup>.

Nel 2017 oltre alle tre campagne di monitoraggio previste nei mesi di marzo, giugno e ottobre, a seguito dell'accordo di collaborazione tecnico-scientifica con l'Università degli Studi di Ferrara<sup>5</sup>, è stata realizzata un'ulteriore campagna nel mese di novembre. L'accordo della durata di 18 mesi prevede, tra le altre cose, l'esecuzione di indagini isotopiche utili a determinare alcune caratteristiche degli acquiferi, come età, omogeneità e circolazione idrica, necessarie per comprendere meglio il fenomeno della contaminazione.

Il presente documento illustra sinteticamente i risultati delle analisi chimiche eseguite da ARPAV nei campioni prelevati nel mese di ottobre 2018. L'esito delle analisi isotopiche e le elaborazioni previste dall'accordo saranno presentate dall'Università al termine della collaborazione.

<sup>1</sup> Deliberazione della Giunta Regionale n. 962 del 05 luglio 2011. Intervento urgente per contrastare il fenomeno di inquinamento da Mercurio nelle falde acquifere della provincia di Treviso. Attuazione monitoraggio d'indagine (D.M. 260/2010).

<sup>3</sup> MeMo Monitoraggio d'indagine delle acque sotterranee in alcuni comuni della provincia di Treviso per lo studio delle modalità di propagazione del plume di inquinamento da mercurio (Hg) - Relazione conclusiva

<sup>4</sup> Monitoraggio delle acque sotterranee in alcuni comuni della provincia di Treviso per il controllo dell'inquinamento da mercurio (Hg)

<sup>5</sup> Deliberazione del Direttore Generale n. 256 del 26 ottobre 2017.

# 2 | I PUNTI DI MONITORAGGIO

Tra i punti monitorati nell'ambito del progetto MeMo, ne sono stati individuati una ventina come rete di controllo della contaminazione in atto. A seguito dei risultati del monitoraggio del 10 novembre 2014 su dieci punti in comune di Preganziol<sup>1</sup>, il pozzo 6600 di via Schiavonia Nuova è stato sostituito con il 6599 sempre in via Schiavonia Nuova. Quest'ultimo, non essendo più campionabile da fine 2016, è stato sostituito dal pozzo 6642.

Nel mese di ottobre, analogamente a quanto fatto nelle ultime campagne e nell'ambito della già citata convenzione con l'Università di Ferrara, sono stati analizzati ulteriori undici punti rispetto ai 21 della rete di controllo degli ultimi anni (tabella 1 e figura 1). I punti aggiunti sono stati presi in esame al fine di avere una più ampia base informativa per le indagini isotopiche, oggetto della collaborazione con l'Università. In particolare, sono stati reinseriti nel monitoraggio nove punti già analizzati fino al 2013 nell'ambito del progetto MeMo e due nuovi punti: uno a Preganziol e uno a Mogliano Veneto.

# 3 | I PARAMETRI RICERCATI

Il set di parametri ricercati è riportato in tabella 2 e comprende alcuni parametri chimico-fisici (temperatura, pH, ossigeno dissolto, potenziale redox, conduttività), gli ioni principali (calcio, magnesio, sodio, potassio, cloruri, sulfati, bicarbonati, nitrati), alcuni metalli (arsenico, ferro, manganese, mercurio) e alcuni altri elementi (bromuri, iodio, ione ammonio). Per il dettaglio dei risultati analitici si rimanda all'Appendice A.

parametro	sigla	udm
temperatura	T	°C
pH	pH	pH
ossigeno dissolto	DO	mg/L
potenziale redox	Eh	mV
conduttività	CE	µS/cm
calcio	Ca	mg/L
magnesio	Mg	mg/L
sodio	Na	mg/L
potassio	K	mg/L
cloruri	Cl	mg/L
solfati	SO <sub>4</sub>	mg/L
bicarbonati	HCO <sub>3</sub>	mg/L
nitrati	NO <sub>3</sub>	mg/L
bromuri	Br	µg/l
iodio	I	µg/L
ione ammonio	NH <sub>4</sub>	µg/L
arsenico	As	µg/L
ferro	Fe	µg/L
manganese	Mn	µg/L
mercurio	Hg	µg/L
mercurio dissolto	Hgd	µg/L

Tabella 2: Elenco dei parametri analizzati.

# 4

## DISTRIBUZIONE DEL MERCURIO

Le concentrazioni di mercurio misurate in ciascuno dei 32 punti, a partire da gennaio 2012, sono sintetizzate in tabella 3 e rappresentate in figura 2.

La concentrazione di mercurio nel punto 6438 di Treviso nel campionamento del 8 ottobre è risultata anomala e particolarmente elevata ( $42.3 \mu\text{g/L}$ ), è stato pertanto eseguito un secondo campionamento il 12 novembre che ha fatto registrare un valore di  $3.0 \mu\text{g/L}$ , che rappresenta il minimo della serie storica del punto ed è in linea con i valori misurati negli ultimi prelievi.

Rispetto all'intero insieme di dati, è stata effettuata una analisi statistica dell'andamento (trend) nel tempo su tutti i punti (20) le cui serie temporali avessero dati idonei alla valutazione (Appendice B). L'analisi statistica conferma il trend crescente di concentrazione, già evidenziato nei precedenti rapporti, per i pozzi 6598, posto nella parte più meridionale della rete di controllo, e per il pozzo 6488 di Treviso, posto nella parte occidentale (figura 3).

Per i nove punti reinseriti nel monitoraggio a seguito della convenzione con l'Università di Ferrara, già analizzati nel progetto MeMo fino al 2013, l'analisi statistica non è stata applicata in considerazione del ridotto insieme di dati. Tuttavia, dal confronto degli ultimi valori con i precedenti si nota che quattro pozzi posizionati nell'area con trend decrescente (6033 e 6132 a Preganziol, 6332 a Quinto di Treviso e 6438 a Treviso) mostrano una diminuzione nella concentrazione, mentre per gli altri rimane sostanzialmente stabile. In figura 4 è rappresentata la distribuzione nello spazio della concentrazione di mercurio delle ultime quattro campagne realizzate. I risultati analitici completi sono riportati in appendice A.

### 4.1 MERCURIO TOTALE E MERCURIO DISCiolto

In acqua i metalli, e tra questi il mercurio, possono essere presenti disciolti oppure in forma solida, in particelle di dimensioni più o meno grandi presenti in sospensione nell'acqua prelevata. Per avere un'idea della ripartizione del mercurio tra le due forme, disciolta e particolata, nella campagna di ottobre, oltre al mercurio totale è stato determinato anche il mercurio disciolto.

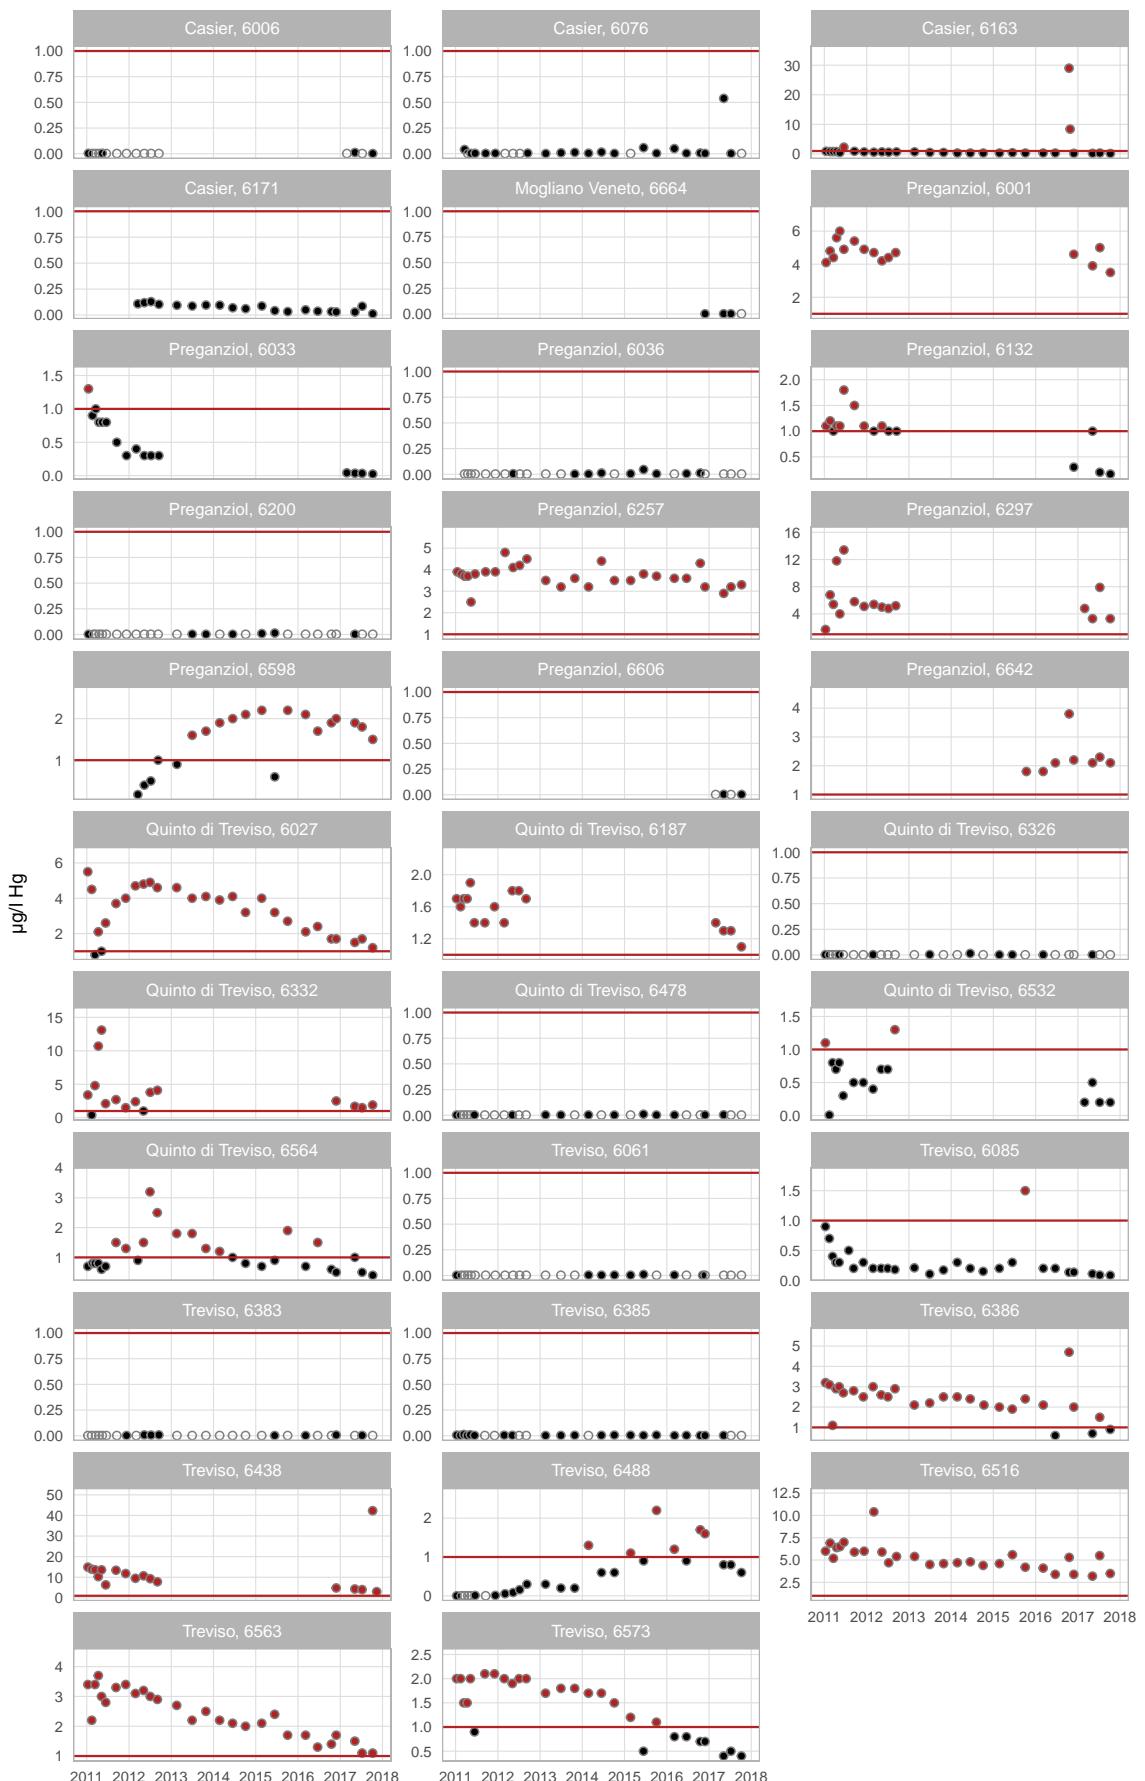

Tra disciolto e particolato la separazione non è netta e si preferisce adottare un criterio pratico per separarli. Il campione viene filtrato su una membrana con fori da  $0.45 \mu\text{m}$ , la frazione che passa è la forma disciolta mentre quella trattenuta è la forma particolata. La somma delle due è il metallo totale.

Dal punto di vista normativo, per le acque destinate al consumo umano, i limiti dei metalli si riferiscono alla concentrazione totale, perché considerati più cautelativi e protettivi, mentre per la valutazione dello stato chimico dei corpi idrici sotterranei i valori soglia si riferiscono alla concentrazione disciolta, questo perché si ritiene che la filtrazione del campione elimini la maggior parte dei solidi sospesi e dei colloidì che sono stati mobilizzati artificialmente durante il campionamento e si valutino così le concentrazioni dei metalli realmente trasportati dall'acqua in forma disciolta.

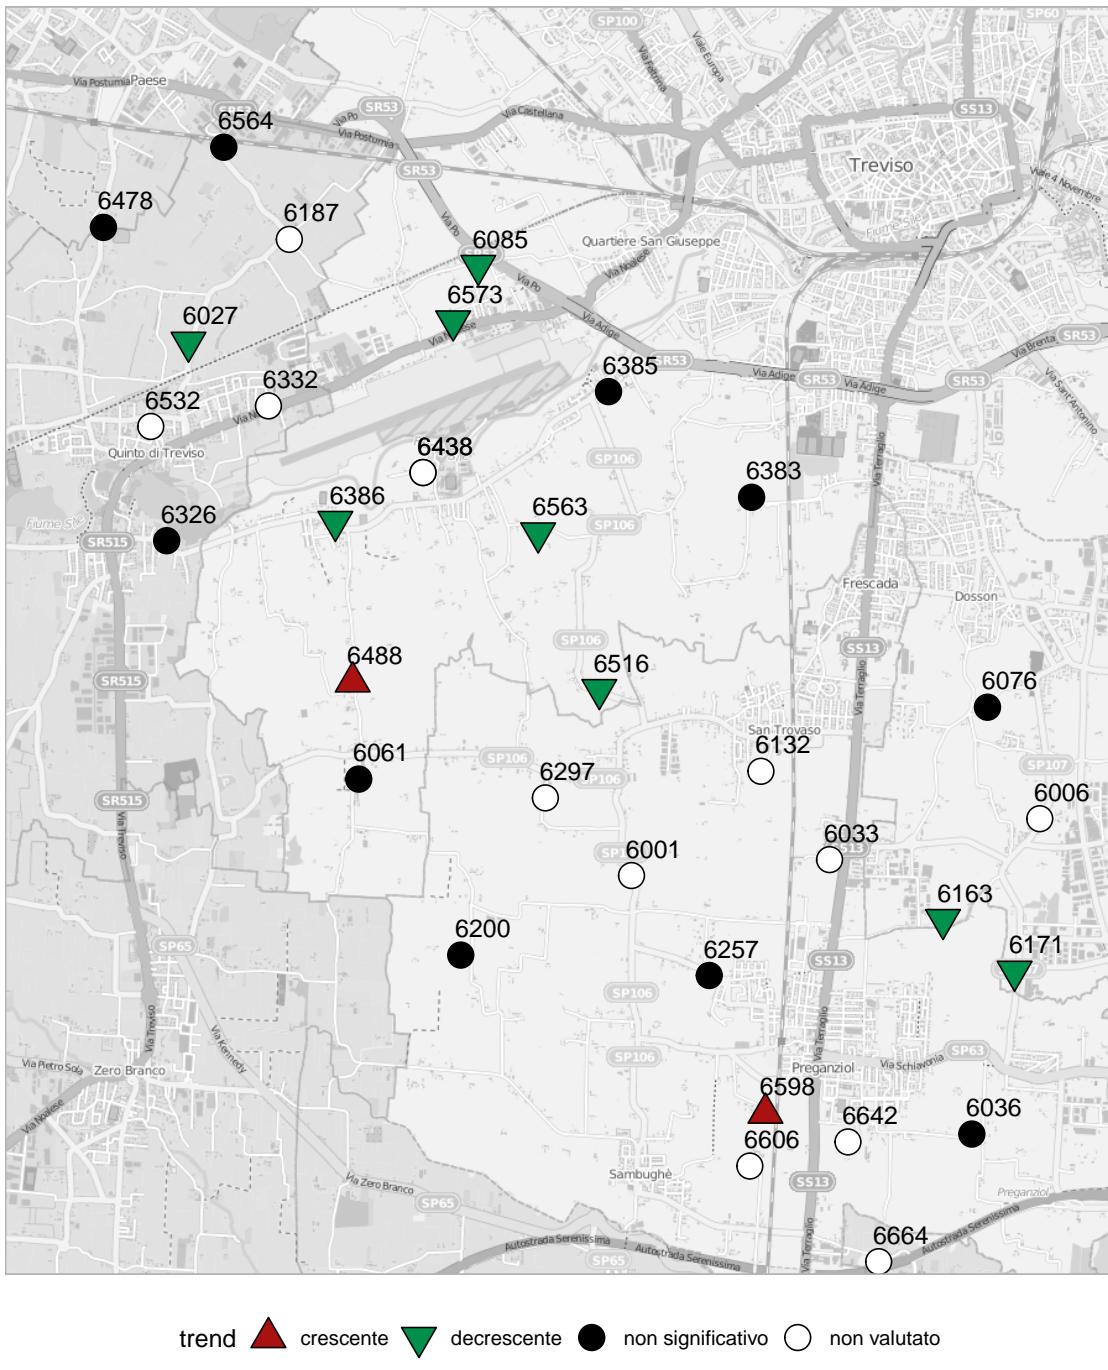

Ecco che a parità di valore numerico di  $1 \mu\text{g/L}$  per entrambe le normative, il valore soglia per le acque sotterranee, riferito alla frazione disciolta, è superato solo nel punto 6332 di Quinto di Treviso, mentre il valore di parametro per le acque destinate al consumo umano, riferito al totale, è superato in 11 punti (figura 5). I risultati indicano che nella maggior parte dei campioni il mercurio è presente nella forma particolata.

**Tabella 3:** Concentrazione mercurio ( $\mu\text{g/L}$ ) nel tempo. (\*) Il punto 6664 è stato analizzato anche ad aprile, maggio e luglio 2017 con valori rispettivamente di 0.029,  $<0.002$  e  $<0.002 \mu\text{g/L}$ .

**Figura 2:** Andamento della concentrazione di mercurio in funzione del tempo. La linea rossa orizzontale individua la concentrazione limite di  $1 \mu\text{g}/\text{L}$  per le acque destinate al consumo umano.

**Figura 3:** Mappa dei risultati dell'analisi di tendenza con il test non parametrico di Mann-Kendall.

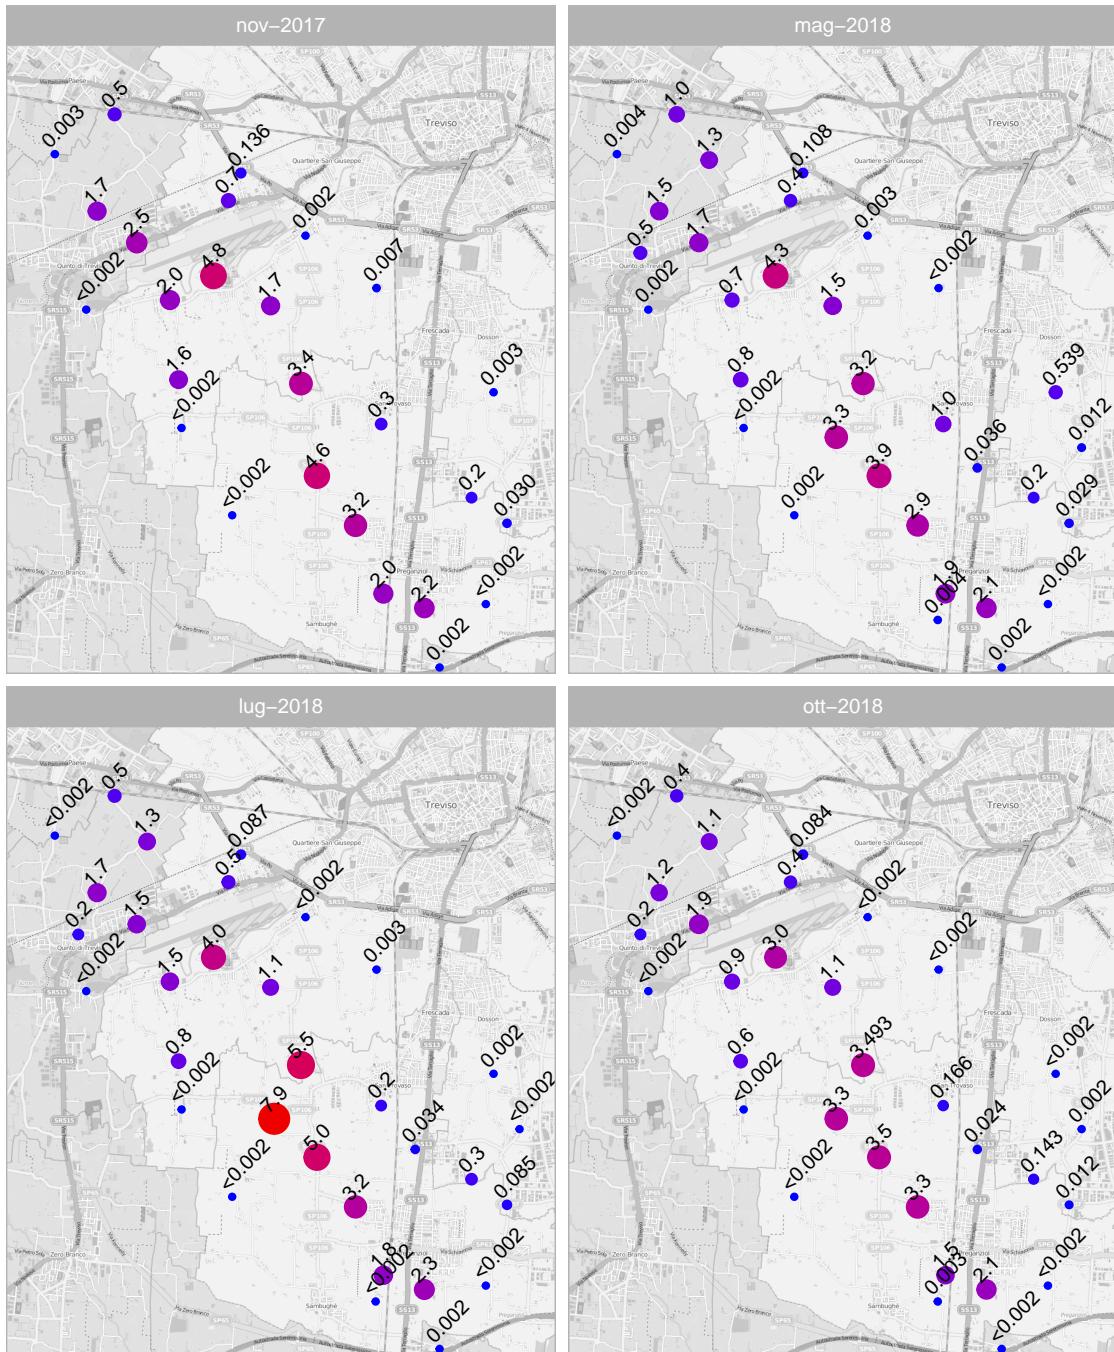

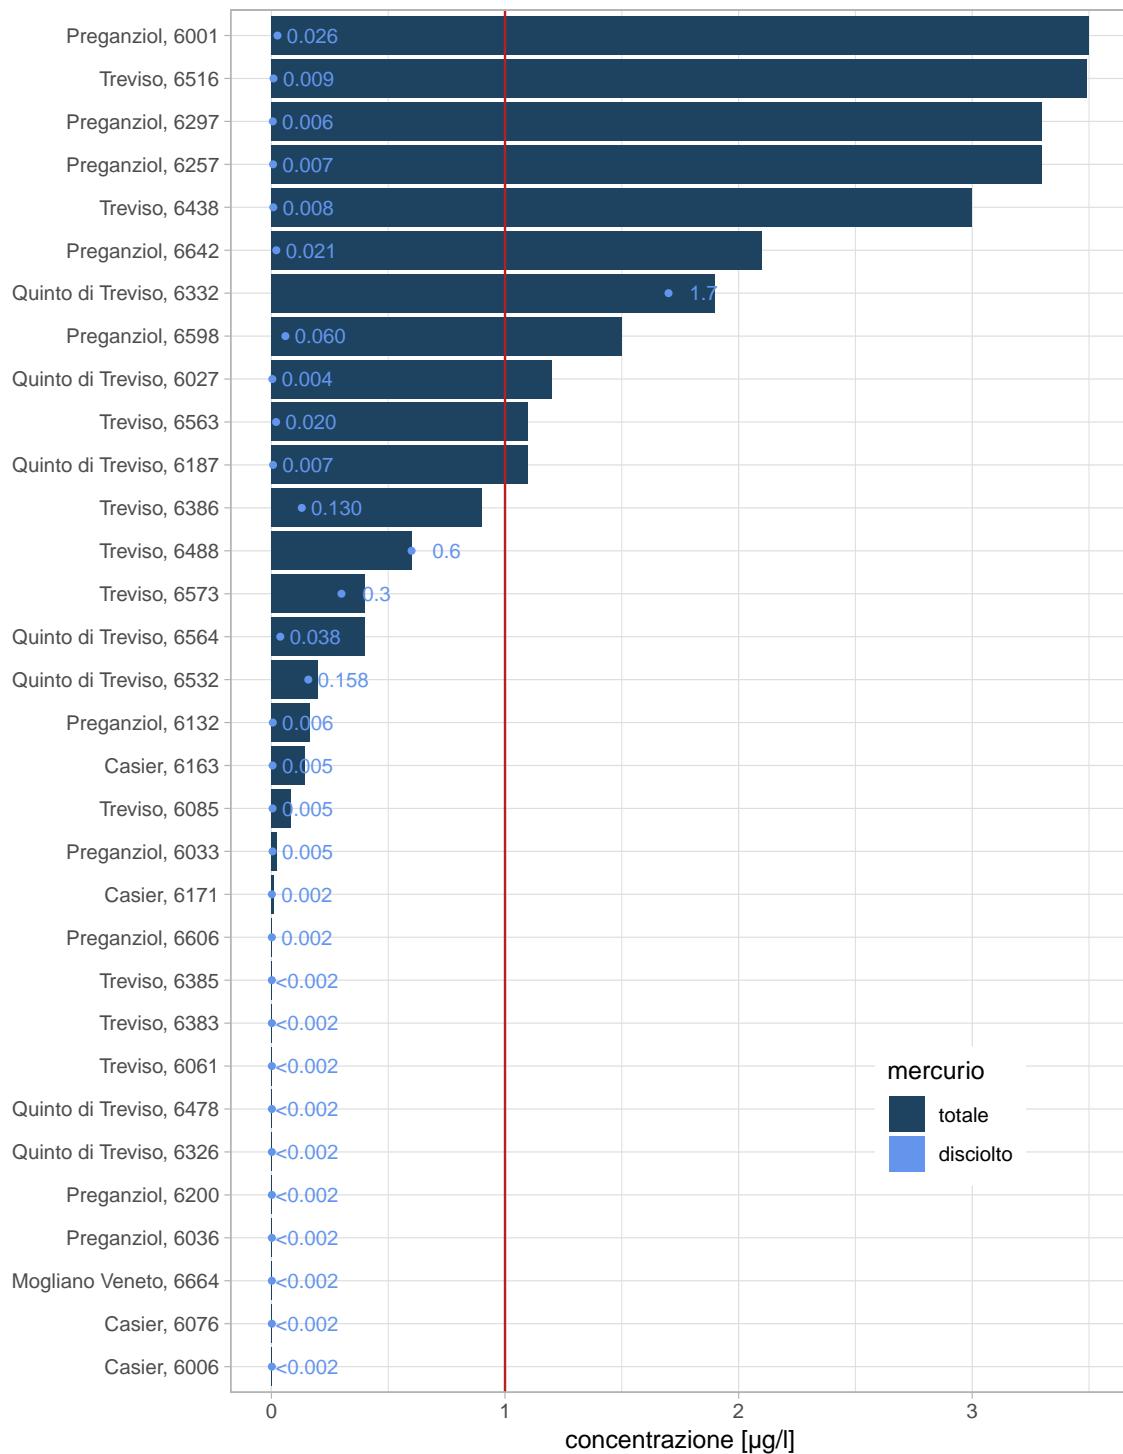

Figura 4: Distribuzione delle concentrazioni di mercurio misurate nelle ultime quattro campagne.

**Figura 5:** Concentrazione del mercurio totale (Hg) e dissolto (Hgd) nei punti di monitoraggio analizzati ad ottobre 2018. La linea rossa verticale individua la concentrazione limite di 1 µg/L per il mercurio totale nelle acque destinate al consumo umano e il valore soglia di 1 µg/L per il mercurio dissolto nelle acque sotterranee.

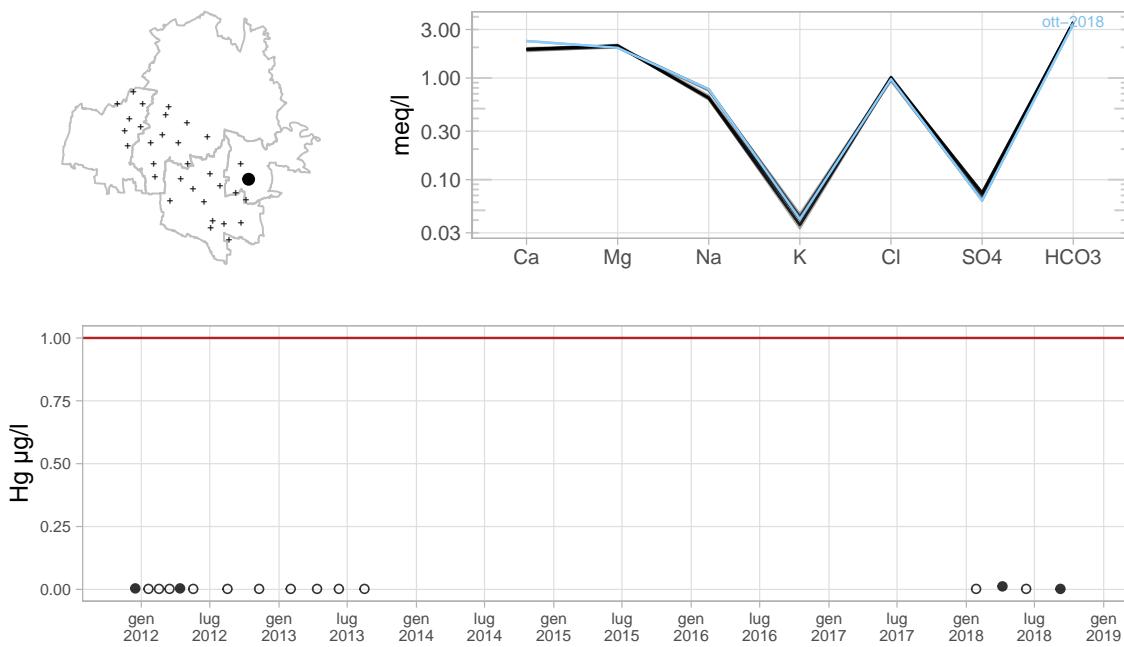

# 5 | SCHEDA SINTESI PUNTO

Per ciascun pozzo è riportata una scheda di sintesi con:

- l'ubicazione all'interno della rete di controllo;
- la composizione chimica dell'acqua di tutti i campioni, compresi quelli analizzati nell'ambito del progetto MeMo, mediante il diagramma di Schoeller<sup>1</sup> ;
- l'andamento nel tempo della concentrazione di mercurio;
- lo storico dei risultati analitici per i parametri ricercati nell'ultima campagna.

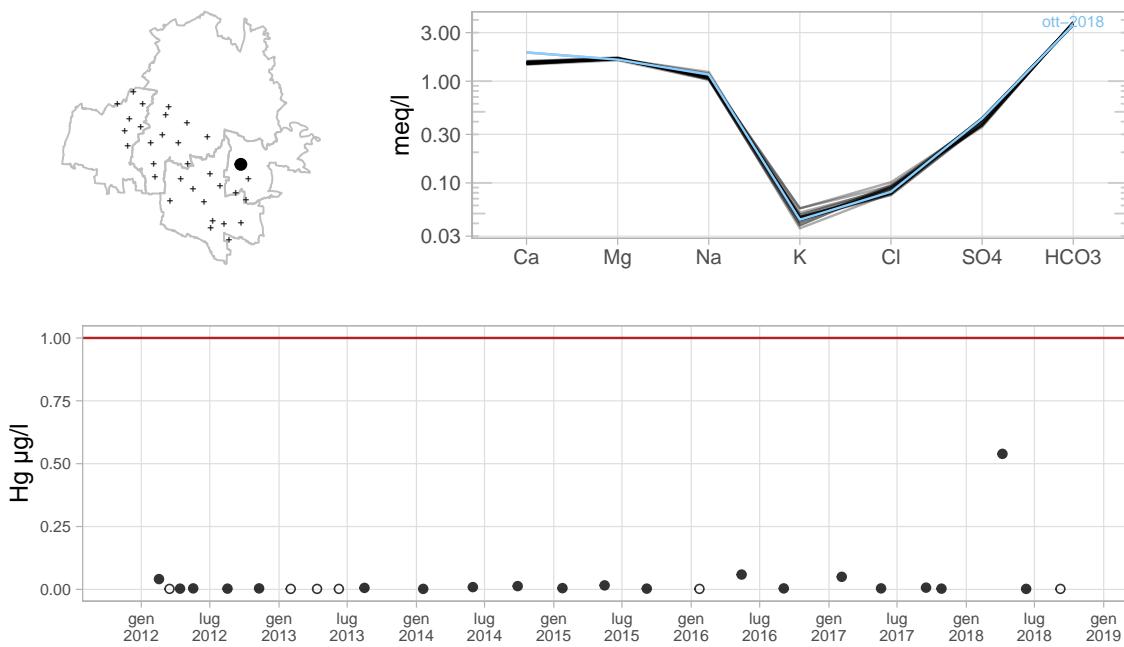

<sup>1</sup> Nel diagramma di Schoeller si riportano in ordinata le concentrazioni ioniche in mEq/l in scala logaritmica ed in ascissa cationi ed anioni. Questo tipo di grafico permette di confrontare con facilità un gran numero di campioni, evidenziando quelli con caratteristiche diverse.

## RISULTATI TEST DI MANN KENDALL

La verifica statistica della presenza di un trend nella concentrazione di mercurio nel singolo pozzo è stata effettuata con il test non parametrico di Mann-Kendall.

È stato scelto il test di Mann-Kendall perché non richiede assunzioni sulla distribuzione statistica dei dati e può essere usato con dataset che includono intervalli di campionamento irregolari, dati mancanti e dati inferiori al limite di quantificazione (basta assegnare un valore comune che sia inferiore al più piccolo valore misurato nel dataset), è robusto rispetto all'eventuale presenza di *outliers*.

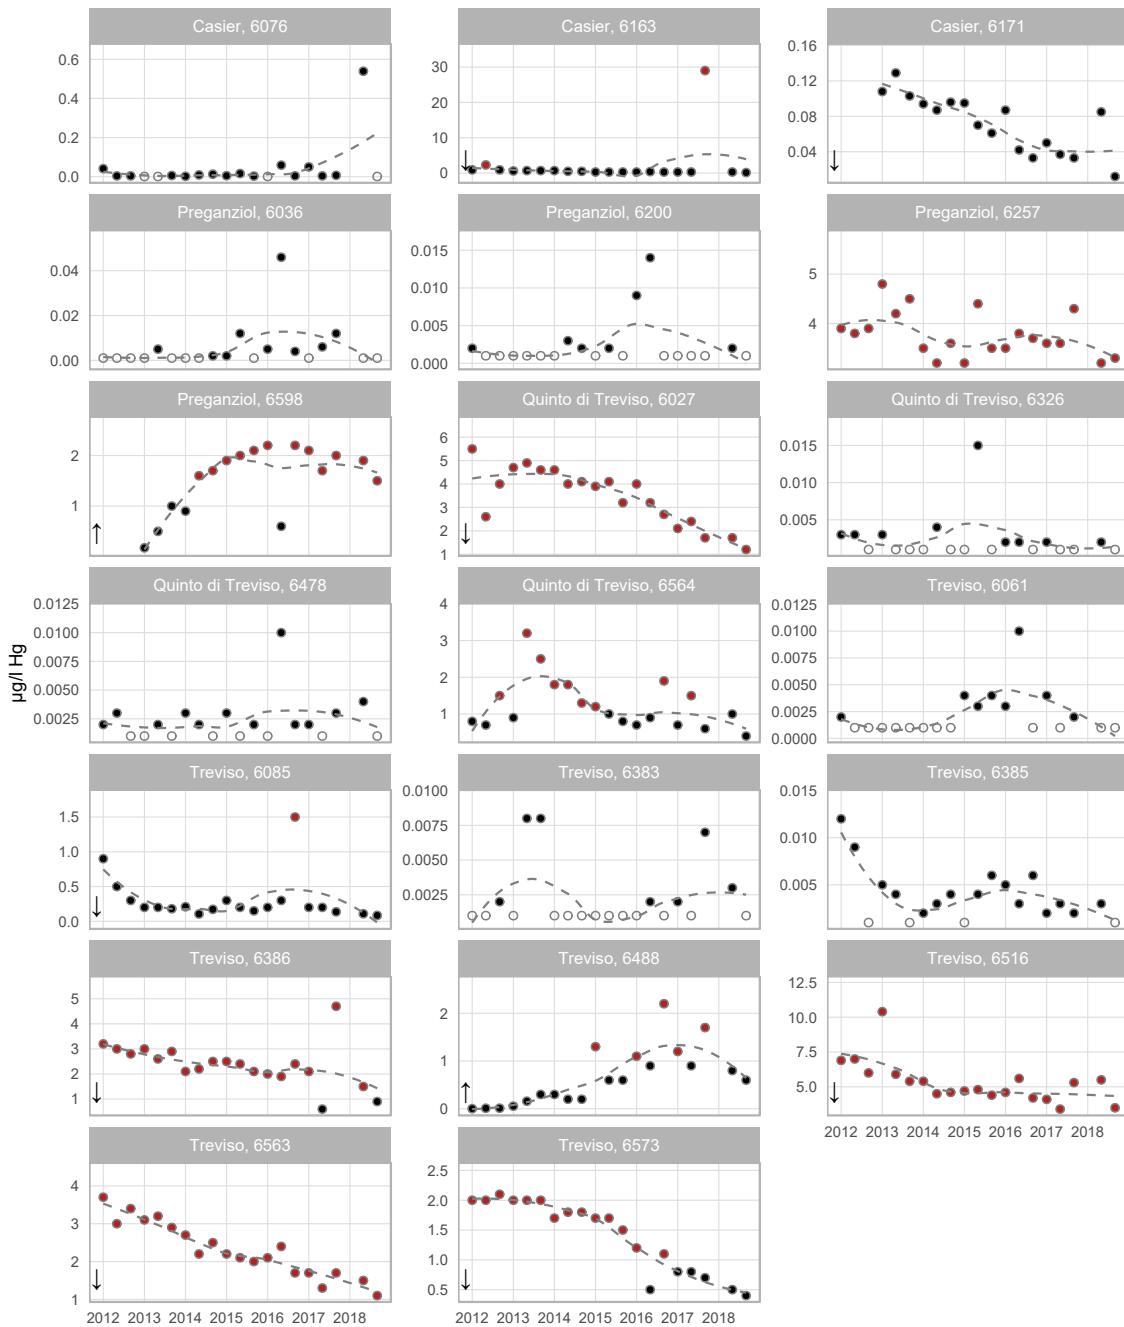

Il test di Mann-Kendall verifica l'esistenza di trend monotoni (lineari e non lineari), ma non quantifica l'entità del trend.

Considerato che la frequenza di campionamento dei dati utilizzati dovrebbe essere quanto più possibile uniforme sul periodo da testare e che il dataset in esame ha raggiunto una numerosità tale da permetterne l'omogeneizzazione, i dati di concentrazione per ciascun punto sono stati ricondotti ad una serie quadrimestrale utilizzando, nel caso ci fossero più osservazioni per uno stesso periodo, il valore massimo.

Il trend è risultato statisticamente significativo ( $p\text{-value}<0.05$ ) e in aumento per i pozzi 6598 e 6488 (tabella 5).

Comune	pozzo	numero dati	S	p-value	tau	trend
Casier	6076	20	26	0.413	0.137	non significativo

Treviso	6516	20	-104	0.001	-0.547	decrescente
Treviso	6563	20	-159	0.000	-0.837	decrescente
Treviso	6573	20	-158	0.000	-0.832	decrescente

Tabella 5: Risultati test di Mann-Kendall.

**Figura 6:** Andamento della concentrazione di mercurio in funzione del tempo dopo l'omogeneizzazione della frequenza di campionamento a quadrimestrale. Le frecce indicano l'esistenza di una tendenza ( $\uparrow$  tendenza crescente,  $\downarrow$  tendenza decrescente), il colore rosso evidenzia i valori di concentrazione superiore al limite di  $1 \mu\text{g}/\text{L}$  per le acque destinate al consumo umano.
